

Guided Architecture Trade Space Exploration of Safety Critical Software Systems

Modern systems are so heavily interconnected that the impacts of component and configuration choices can be difficult to know at design time. In this work, we partially automate the exploration of a system's architectural trade space to enable system designers to rapidly evaluate system design options. The result is a graphical, user-guided suite of tools that enables a 'design-by-shopping' style of system design.

We build on SEI's existing work in high-fidelity system architecture modeling.

In previous work, the SEI created the *Architecture Analysis and Design Language* (AADL), which enables the creation of very detailed models of a system's architecture. The SEI also maintains the *Open Source Architecture Tool Environment* (OSATE), which contains a number of analyses for AADL models, ranging from weight and latency calculations to sophisticated projections of system error-behavior.

A system's architectural trade space is the set of all possible candidate designs plotted in n-dimensional space where each dimension is a different quality attribute.

Penn State's ARL Trade Space Visualizer (ATSV) enables designers to visually explore multidimensional and potentially infinite data sets. It uses an evolutionary algorithm to learn which input characteristics correspond to which outputs; this lets designers refine their searches and generate additional candidate architectures that meet particular criteria.

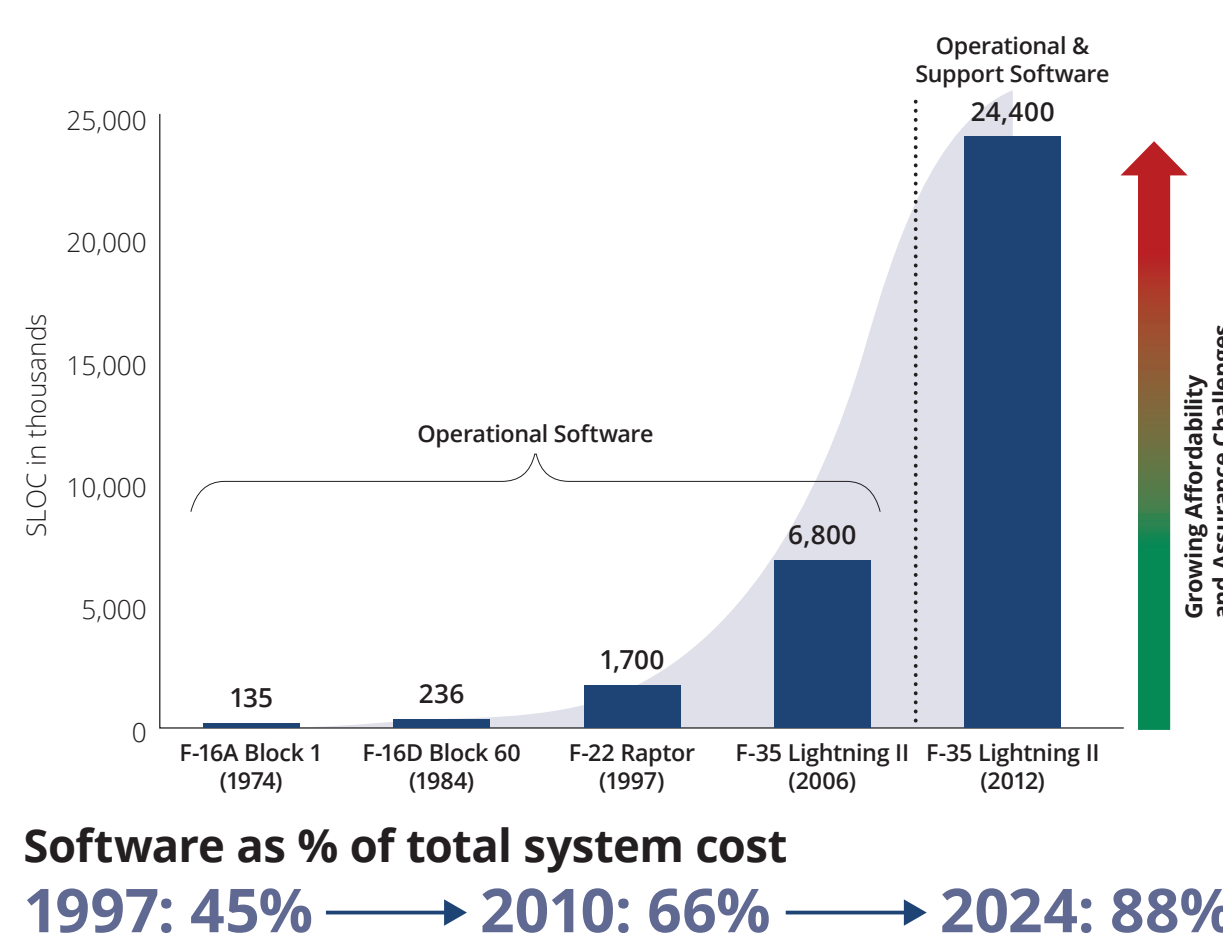

2. Designers can refine their searches, and ATSV will generate more candidate architectures in the reduced search area. This is done automatically, using an evolutionary algorithm to learn which input values correspond to which outputs.

This work has three primary tasks:

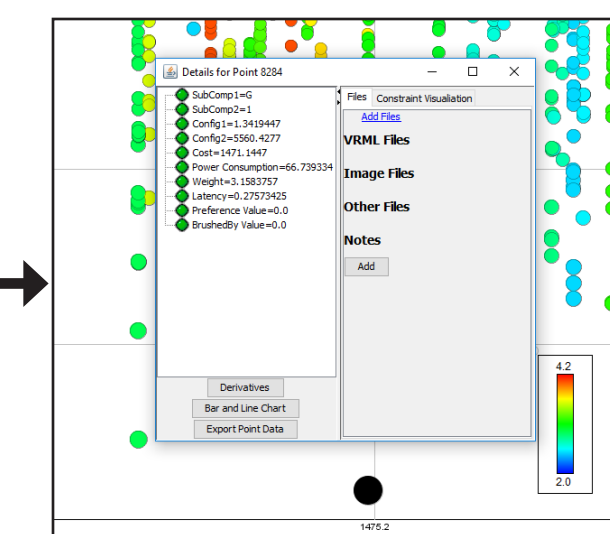

1. Extend existing architecture modeling language (SEI's AADL) to encode component choices and their interactions.
2. Extend existing architecture modeling tooling (SEI's OSATE) to automatically analyze the resulting system for cost, weight, performance, etc.
3. Enable trade space visualizer (Penn State's ATSV) to automatically select valid components and configurations, and visually display analysis results.

Why do we need something new?

System development costs are rising at an unsustainable rate. Much of this rise is driven by software, which presents a number of unique challenges in terms of massive customizability/configurability and subtle interactions with other components. SEI's work in system architecture modeling addresses this need head-on by modeling software, hardware, and the bindings between the two.

3. Once a satisfactory architecture has been identified, the designer can click the point to reveal the component and configuration options chosen, as well as exact quality attribute values for each dimension.

How does 'design-by-shopping' work?

Much like traditional shopping, design-by-shopping begins with a broad search of candidates that potentially meet some need. Individual candidates are evaluated according to attributes like cost, performance, weight, power, etc. If none of the candidates are satisfactory, more can be generated – or the trade space can be refined to focus the search. If one of the candidates is satisfactory, though, then the designer can view its exact configuration and proceed to more detailed modeling and analysis.

This work is an enabling technology for future architecture modeling research at the SEI.

Any quantitative analysis can be used as a dimension of the trade space visualization. Sophisticated new analyses for AADL are being created in OSATE to analyze complex system properties like safety and security. Once built, it's relatively straightforward to automate these analyses and connect them to ATSV.

This project combines a number of technologies to enable a new paradigm of system design. As it relies heavily on quantitative analyses of system architectures, in the future we will look into novel quantification strategies for traditionally qualitative attributes like safety and security.
